

Introduction

- No formal security training
- Software industry since 1999
- Focus on security since 2011
- Worked for BOM, Red Hat, Console, SpiderLabs
- Ask me about Best Korea
- Free solo climber (i.e. insane)
- I love finding new 0day and popping shells

Outline

- Java (de)serialization
- RCE via XML deserialization
- RCE via native deserialization
- RCE via XML <-> binary mapping vector
- Other InvocationHandlers?
- "Property-oriented programming" and gadgets
- Where lies the vulnerability?

Java (de)serialization

- Java has multiple serialization implementations
- XML serialization: XXE and RCE possible in multiple implementations
- Native serialization: binary data format, with RCE possible depending on what's on the classpath
- Dozer, Kryo, and other frameworks
- Common thread: don't deserialize untrusted input (duh!)

RCE – XML deserialization

- Alternative XML-based serialization formats
- JAXB is the standard (possible same vector as native)
- Other XML serialization libraries exist, and have exposed security issues leading to RCE
- These are commonly used by big applications and XML REST API frameworks
- We'll look at just two examples: XMLDecoder and XStream
- NOT reliant on classes implementing Serializable

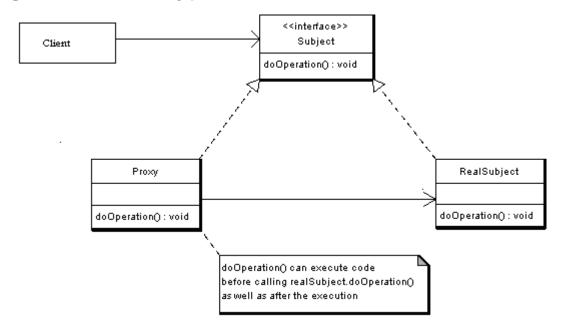

XMLDecoder

- XMLDecoder's XML format can represent a series of methods that will be called to reconstruct an object
- If XMLDecoder is used to deserialize untrusted input, arbitrary code can be injected into the XML

Live demo: Restlet CVE-2013-4221. Fixed by removing vulnerable functionality.

XStream

- Reflection-based deserialization
- Has a special handler for dynamic proxies (implementations of interfaces)
- Spring OXM, Sonatype Nexus, Jenkins, etc. affected

XStream

- Attackers can provide XML representing a dynamic proxy class, which implements the interface of a class the application might expect
- Dynamic proxy implements an EventHandler that calls arbitrary code when any members of the deserialized class are called

XStream in Jenkins

- Jenkins XML API uses XStream to deserialize input
- Access to XML API => RCE (but not such a huge deal)
- Live demo: Jenkins
- Solution: blocked DynamicProxyConverter in XStream wrapper class
- Upstream solution: whitelisting, with dynamic proxies excluded by default
- More information: https://securityblog.redhat.com/2014/01/23/java-deserialization-flaws-part-2-xml-deserialization/

RCE – binary deserialization

- Java contains a native serialization mechanism, that converts objects to binary data
- When deserializing, the readObject() and readResolve() methods of the class will be called
- This can lead to vulnerabilities if a class on the classpath has something exploitable in readObject() or readResolve()
- How can an attacker provide binary serialized objects?

RCE – binary deserialization

- Serialization is used as a format for transferring objects over networks, e.g. via REST APIs
- Example #1: RichFaces state (CVE-2013-2165, Takeshi Terada, MBSD)

- Example #2: Restlet REST framework
- Live demo: Restlet PoC
- What kind of issue could exist in readResolve() or readObject() that would be exploitable?

CVE-2011-2894: Spring AOP

- Discovered by Wouter Coekaerts, first known vulnerability in this category
- Serializable InvocationHandler exposed
- Allows mapping a proxy to ANY method call on the proxy interface
- Similar exploit to EventHandler, but more complex setup of the serialized object graph
- More information: http://www.pwntester.com/blog/2013/12/16/cve-2011-2894-deserialization-spring-rce/

Commons-fileupload

- Component to simplify file uploads in Java apps
- DiskFileItem class implements readObject()
- The readObject method creates a tmp file on disk: tempFile = new File(tempDir, tempFileName);
- tempDir is read from the "repository" private attribute of the class, exposing a poison null byte flaw (file-writing code is native, now patched in the JDK)
- An attacker can provide a serialized instance of DFI with a nullterminated full path value for the repository attribute: /path/to/file\0
- Commons-fileupload code embedded in Tomcat

Restlet + DFI

- Upload a JSP shell to achieve RCE
- Solution #1: don't deserialize untrusted content
- Solution #2: don't introduce flaws in readObject() or readResolve()
- Solution #3: type checking with look-ahead deserialization (Pierre Ernst): http://www.ibm.com/developerworks/java/library/se-lookahead/index.html

Or notsoserial: https://tersesystems.com/2015/11/08/closing-the-open-door-of-java-object-serialization/

Dozer XML <-> Binary Mapper

- Uses reflection-based approach to type conversion
- Used by e.g. Apache Camel to map types
- If used to map user-supplied objects, then an attacker can provide a dynamic proxy
- There must either be an object being mapped to with a getter/setter method that matches a method in an interface on the server classpath, or a manual XML mapping that allows an attacker to force the issue
- InvocationHandler must implement Serializable interface
- EventHandler does not implement it

Dozer CVE-2014-9515

- Wouter Coekaerts reported a serializable InvocationHandler in older versions of Spring AOP (CVE-2011-2894)
- Using Alvaro Munoz's CVE-2011-2894 exploit, I was able to develop a working Dozer exploit. It is only exploitable if all the aforementioned conditions are met, and vulnerable Spring JARs are on the classpath.
- Live demo: Dozer RCE
 https://github.com/pentestingforfunandprofit/research/tree/master/dozer-rce
- Reported upstream in Dec 2014, no response: https://github.com/DozerMapper/dozer/issues/217

Other Invocation Handlers

- Any common component is useful, but in the JDK itself means more universally exploitable
- CompositeDataInvocationHandler: forwards getter methods to a CompositeData instance. No use.
- Three other InvocationHandlers in Java 7/8:
 - CompositeDataInvocationHandler
 - MBeanServerInvocationHandler
 - RemoteObjectInvocationHandler

MBeanServletInvocationHandler

- Proxy to an MBean on the server. Potentially useful, e.g. if MBeans used by the JBoss Worm are present (allowing RCE)
- Problem 1: attacker must specify correct JMX URL
 - Solution 1: JMX is exposed locally on port 1099
 - Solution 2: Brute for JMX URL via Java PID
- Problem 2: attacker cannot control code that is run for any method call, only specific method calls
- EventHandler exploits work no matter which method is invoked on the proxy object. MBeanServerInvocationHandler simply calls the method of the same name on the MBean.

RemoteObjectInvocationHandler

- Proxy to a remote object exported via RMI
- Problem 1: attacker must know details of a remote object exported to the server
 - Solution: JMX registry is exposed via RMI. If JMX is exposed locally on port 1099, the attacker could craft an object instance that points to the JMX RMI URL
- Problem 2: attacker cannot control code that is run for any method call, only specific method calls
- Future work: look for more potentially exploitable InvocationHandlers in other libraries

Property-oriented programming

- Instantiate a complex object graph whose root node is serializable
- Similar to ROP, exploit conditions in classes on the classpath so deserialization of the object graph lands in execution of arbitrary code
- Shout outs to Stefan Esser for considering this in PHP first
- http://www.slideshare.net/frohoff1/appseccali-2015-marshallingpickles slide 45 onward

Gadget: commons-collection

- Serializable InvocationHandler in a library that is almost universally on the classpath
- Presented at AppSecCali:
 <u>http://www.slideshare.net/codewhitesec/exploiting-deserialization-vulnerabilities-in-java-54707478</u>
- FoxGlove reported multiple vectors for untrusted deserialization in JBoss, WebSphere, Jenkins, WebLogic, etc. http://foxglovesecurity.com/2015/11/06/what-do-weblogic-websphere-jboss-jenkins-opennms-and-your-application-have-in-common-this-vulnerability/

Tools & future research

- Ysoserial for finding flaws and aggregating payloads
- Look-ahead deserialization tools:
 - PoC by Pierre Ernst @ IBM
 - Notsoserial
 - Serialkiller
- Is JAXB similarly exploitable?
- More gadgets, more deserialization vectors
- Gadget entirely in the JDK would be awesome and Wouter has delivered:
 - http://wouter.coekaerts.be/2015/annotationinvocationhandler

Where lies the vulnerability?

 When at Red Hat, I assigned CVEs to vulnerable classes, and publicly stated:

Note that exploitation of the DiskFileItem flaw relies on an application performing deserialization of untrusted data, with DiskFileItem on the classpath. Does the flaw lie in the application performing deserialization of untrusted data, which in isolation is not a security concern? Or does it lie in DiskFileItem, which is not vulnerable unless an application is performing deserialization of untrusted data? This is a question which does not yet have a consensus answer in the security community. The Red Hat Security Response Team's view is that both a vulnerable serializable class, and an application performing deserialization of untrusted data expose security flaws. Therefore we assigned CVE-2013-2186 to the DiskFileItem flaw. This view is not shared by the Apache Commons security team, who viewed the fix as a hardening measure, and that only an application performing deserialization of untrusted data would expose an actual security flaw.

Where lies the vulnerability

- I was wrong (shock, horror!)
- The vulnerability lies in the application performing deserialization of untrusted data without look-ahead type validation

Thomas Patzke @blubbfiction · 17h

Blaming Apache commons-collection for RCE is like blaming a lib used in a ROP exploit. Most misunderstood bug of this year.
